1.4 — Data Wrangling in the tidyverse

ECON 480 • Econometrics • Fall 2021

Ryan Safner

Assistant Professor of Economics

- safner@hood.edu
- <u>ryansafner/metricsF21</u>
- metricsF21.classes.ryansafner.com

tibble: friendlier dataframes

magrittr: piping code

readr: importing data

dplyr: wrangling data

<u>dplyr::filter(): select observations</u>

<u>dplyr::arrange(): reorder observations</u>

<u>dplyr::select(): select variables</u>

<u>dplyr::rename(): rename variables</u>

<u>dplyr::mutate(): create new variables</u>

<u>dplyr::summarize(): create statistics</u>

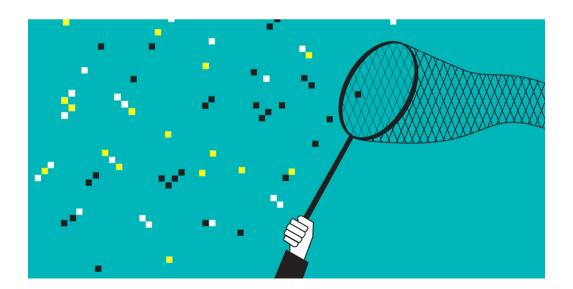

tidyr: reshaping data

<u>dplyr: combining datasets</u>

Data Wrangling

- Most data analysis is taming chaos into order
 - Data strewn from multiple sources
 - ∘ Missing data ("NA") 😡
 - o Data not in a readable form 😉

Workflow of a Data Scientist I

- 1. Import raw data from out there in the world
- 2. Tidy it into a form that you can use
- 3. Explore the data (do these 3 repetitively!)
 - Transform
 - Visualize
 - Model
- 4. **Communicate** results to target audience

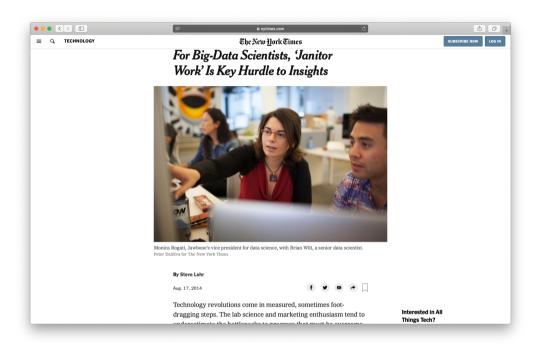

Ideally, you'd want to be able to do all of this in one program

R for Data Science

Workflow of a Data Scientist II

New York Times

"Yet far too much handcrafted work - what data scientists call "data wrangling," "data munging," and "data janitor work" - is still required. Data scientists, according to interviews and expert estimates, spend from 50 to 80 percent of their time mired in this more mundane labor of collecting and preparing unruly digital data, before it can be explored for useful nuggets."

tidyverse

The tidyverse I

"The tidyverse is an opinionated collection of R packages designed for data science. All packages share an underlying design philosophy, grammar, and data structures.

- Allows you to do all of those things with one (set of) package(s)!
- Learn more at <u>tidyverse.org</u>

The tidyverse II

- Easiest to just load the core tidyverse all at once
 - First install may take a few minutes installs a lot of packages!
 - Note loading the tidyverse is "noisy", it will spew a lot of messages
 - Hide them with suppressPackageStartupMessages() and insert library()
 command inside

```
# install for first time
# install.packages("tidyverse") # this takes a few minutes and may give several prompts
# load tidyverse
suppressPackageStartupMessages(library("tidyverse"))
```

The tidyverse III

tidyverse_packages()

[29] "xml2"

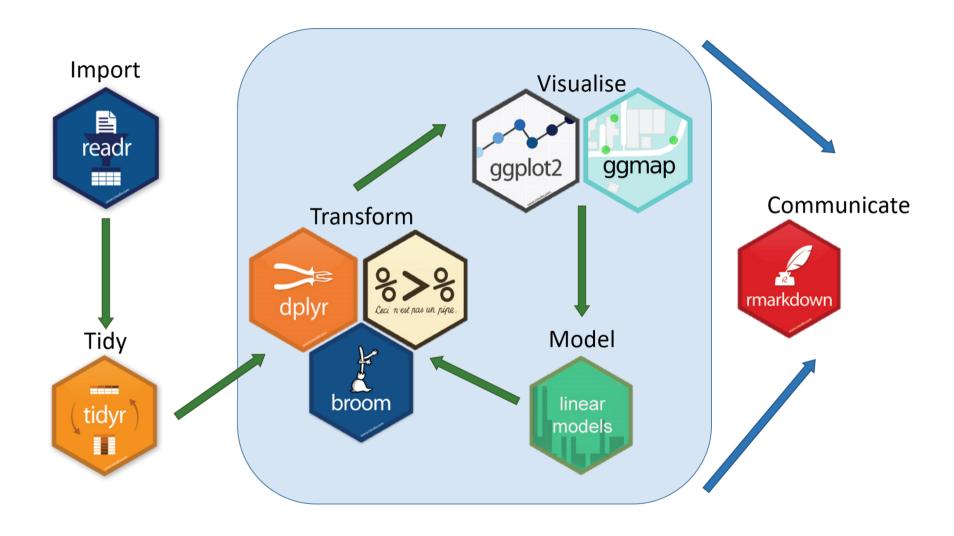

• tidyverse contains a lot of packages, not all are loaded automatically

```
"cli"
       "broom"
                                          "crayon"
                                                          "dbplyr"
##
    [5] "dplyr"
                         "dtplyr"
                                          "forcats"
                                                          "googledrive"
##
    [9] "googlesheets4" "ggplot2"
                                          "haven"
                                                          "hms"
## [13] "httr"
                         "jsonlite"
                                          "lubridate"
                                                          "magrittr"
## [17] "modelr"
                         "pillar"
                                          "purrr"
                                                          "readr"
                         "reprex"
                                          "rlang"
## [21] "readxl"
                                                          "rstudioapi"
## [25] "rvest"
                         "stringr"
                                          "tibble"
                                                          "tidyr"
                         "tidyverse"
```

Your Workflow in the tidyverse:

Tidyverse Packages

- We will make **extensive** use of (and talk today about):
- 1. tibble for friendlier dataframes
- 2. magrittr for "pipeable" code
- 3. readr for importing data
- 4. dplyr for data wrangling
- 5. tidyr for tidying data
- 6. ggplot2 for plotting data (we've already covered)
- We will (or might) later look at:
- 1. **broom** for tidy regression (not part of core tidyverse)
- 2. forcats for working with factors
- 3. stringr for working with strings
- 4. lubridate for working with dates and times
- 5. purrr for iteration

tibble: friendlier dataframes

tibble I

• tibble converts all data.frames into a friendlier version called tibbles (or tbl_df)

tibble II

diamonds

```
## # A tibble: 53,940 × 7
                       color clarity depth table price

       0.23 Very Good H
                             VS1
                                       59.4
                                               61
                                                     338
## # ... with 53,930 more rows
```

- Prints much nicer output
- Shows a bit of the structure:

```
o nrow() x ncol()
o <dbl> is numeric ("double")
o <ord> is an ordered factor
o <int> is an integer
```

- Fundamental grammar of tidyverse:
 - 1. start with a tibble
 - 2. run a function on it
 - 3. output a new tibble

tibble III

• Create a tibble from a data.frame with as_tibble()

```
as_tibble(mpg) # take built-in dataframe mpg
```

• Create a tibble from scratch with tibble(), works like data.frame()

tibble IV

• Create a tibble row-by-row with tribble()

```
example_2<-tribble(
    ~x, ~y, ~color, # each variable name starts with ~
    2, 1.5, "orange",
    4, 0.2, "green",
    6, 0.8, "blue") # last element has no comma
example_2</pre>
```

magrittr: piping code

magrittr I

- The magrittr package allows us to use the "pipe"
 operator (%>%)[†]
- %>% "pipes" the *output* of the *left* of the pipe *into* the *(1st)* argument of the *right*
- Running a function f on object x as f(x) becomes x
 %>% f in pipeable form
 - i.e. "take x and then run function f on it"

^{*}Keyboard shortcuts in R Studio: CTRL+Shift+M (Windows) or Cmd+Shift+M (Mac)

magrittr II

• With ordinary math functions, read from outside \leftarrow (inside):

- \circ i.e. take x and perform function f() on x and then take that result and perform function g() on it
- With pipes, read operations from left → right:

```
x %>% f %>% g
```

take x and then perform function f on it, then perform function g on that result

• Read %>% mentally as "and then"

magrittr III

Example

- First, exponentiate x, then take the natural log of that (resulting in just x)
- In pipes:

```
x %>% exp() %>% ln()
```

magrittr IV

Example

- Sequence: find keys, unlock car, drive to school, park
- Using nested functions in pseudo-"code":

```
park(drive(start_car(find("keys")), to = "campus"))
```

• Using pipes:

```
find("keys") %>%
  start_car() %>%
  drive(to = "campus") %>%
  park()
```

magrittr: Simple Example

```
# look at top 6 rows
head(gapminder)

# use pipe instead
gapminder %>% head()
```

##	#	A tibble: 6	× 6				
##		country	continent	year	lifeExp	pop	gdp
##		<fct></fct>	<fct></fct>	<int></int>	<dbl></dbl>	<int></int>	
##	1	Afghanistan	Asia	1952	28.8	8425333	
##	2	Afghanistan	Asia	1957	30.3	9240934	
##	3	Afghanistan	Asia	1962	32.0	10267083	
##	4	Afghanistan	Asia	1967	34.0	11537966	
##	5	Afghanistan	Asia	1972	36.1	13079460	
##	6	Afghanistan	Asia	1977	38.4	14880372	

magrittr: More Involved Example

- These two methods produce the same output (average hightway mpg of Audi cars)
- Without the pipe

```
summarise(group_by(filter(mpg, manufacturer=="audi"), model), hwy_mean = mean(hwy))
```

Using the pipe

```
mpg %>%
  filter(manufacturer=="audi") %>%
  group_by(model) %>%
  summarise(hwy_mean = mean(hwy))
```

readr: importing data

readr

- readr helps load common spreadsheet files (.csv, .tsv) with simple commands:
- read_*(path/to/my_data.*)
 - o where * can be .csv or .tsv
- Often this is enough, but many more customizations possible
- You can also export your data from R into a common spreadsheet file with:
- write_*(my_df, path = path/to/file_name.*)
 - where my_df is the name of your tibble, and file_name is the name of the file you want to save as

Readxl and Haven: When Readr isn't Enough

- For other data types from software programs like Excel, STATA, SAS, and SPSS:
- readxl has equivalent commands for Excel data types:

```
o read_*("path/to/my/data.*")
o write_*(my_dataframe,
   path=path/to/file_name.*)
o where * can be .xls or .xlsx
```

haven has equivalent commands for other data types:

```
o read_*("path/to/my_data.dta") for STATA .dta files
o write_*(my_dataframe,
    path=path/to/file_name.*)
o where * can be .dta (STATA), .sav (SPSS), .sas7bdat (SAS)
```

Common Import Issues I

- Most common: "where the hell is my data file"??
- Recall R looks for files to read_*() in the default working directory (check what it is with getwd(), change it with setwd())
- You can tell R where this data is by making the path a part of the file's name when importing
 - ∘ Use ... to "move up one folder"
 - Use / to "enter a folder"
- Either use an **absolute path** on your computer:

```
# Example

df <- read_csv("C:/Documents and Settings/Ryan Safner/Downloads/my_data.csv")</pre>
```

Common Import Issues II

- Most common: "where the hell is my data file"??
- Recall R looks for files to read_*() in the default working directory (check what it is with getwd(), change it with setwd())
- You can tell R where this data is by making the path a part of the file's name when importing
 - Use ... to "move up one folder"
 - Use / to "enter a folder"
- Or use a **relative path** from R's working directory

```
# Example
# If working directory is Documents, but data is in Downloads, like so:
#
# Ryan Safner/
# |- Documents/
# |- Downloads/
# |- Photos/
# |- Videos/
df <- read_csv("../Downloads/my_data.csv")</pre>
```

Common Import Issues III

- **Suggestion** to make your data import easier: *Download and move files to R's working directory*
- Your computer and working directory are different from mine (and others)
- This is not a reproducible workflow!
- We'll finally fix this next class with R Projects
 - The working directory is set to the Project Folder by default
 - Same for everyone on any computer!

dplyr: wrangling data

dplyr I

- dplyr uses more efficient & intuitive commands to manipulate tibbles
- Base R grammar passively runs functions on nouns: function(object)
- dplyr grammar actively uses verbs: verb(df, conditions) †
- Three great features:
- 1. Allows use of %>% pipe operator
- 2. Input and output is always a tibble
- 3. Shows the output from a manipulation, but does not save/overwrite as an object unless explicitly assigned to an object

^{*}With the pipe, even simpler: df %>% verb(conditions)

dplyr II

• Common dplyr verbs

Verb	Does
filter()	Keep only selected <i>observations</i>
select()	Keep only selected <i>variables</i>
<pre>arrange()</pre>	Reorder rows (e.g. in numerical order)
<pre>mutate()</pre>	Create new variables
<pre>summarize()</pre>	Collapse data into summary statistics
group_by()	Perform any of the above functions by groups/categories

dplyr::filter(): select observations

dplyr::filter()

• filter keeps only selected **observations** (rows)

```
# look only at African observations
# syntax without the pipe
filter(gapminder, continent=="Africa")
```

```
# using the pipe
gapminder %>%
filter(continent == "Africa")
```

```
## # A tibble: 624 × 6
                          year lifeExp
                                            pop gdpPercap
##

## # ... with 614 more rows
```

dplyr: saving and storing outputs I

- dplyr functions never modify their inputs (i.e. never overwrite the original tibble)
- If you want to save a result, use <- to assign it to a new tibble
- If assigned, you will not see the output until you call up the new tibble by name

```
# base syntax
africa <- filter(gapminder,</pre>
                  continent=="Africa")
# using the pipe
africa <- gapminder %>%
 filter(continent == "Africa")
# look at new tibble
africa
```

```
## # A tibble: 624 × 6
##
      country continent
                         year lifeExp
                                            pop gdpPercap
                                 <dbl>
                                          <int>
                                                    <dbl>
      <fct> <fct>
                         <int>
    1 Algeria Africa
                         1952
                                 43.1 9279525
                                                    2449.

                                                   4797.
```

dplyr: saving and storing outputs III

• If you were to assign the output to the original tibble, it would *overwrite* the original!

dplyr Conditionals

- In many data wrangling contexts, you will want to select data conditionally
 - To a computer: observations for which a set of logical conditions are TRUE[†]
 - >, <: greater than, less than</p>
 - >=, <=: greater than or equal to, less than or equal to
 - $\circ == \ddagger$, !=: is equal to \ddagger , is not equal to
 - \circ %in%: is a member of some defined set (\in)
 - &: AND (commas also work instead)
 - ∘ : OR
 - : not

[†]See ?Comparison and ?Base::Logic.

[‡] Recall one = assigns values to an object, two == tests an object for a condition!

dplyr::filter() with Conditionals

dplyr::mutate(): create new variables

dplyr::mutate()

- mutate creates a new variable (column)
 - o always adds a new column at the end
 - o general formula: new_variable_name = operation

dplyr::mutate() II

- Three major types of mutates:
- 1. Create a variable that is a specific value (often categorical)

```
## # A tibble: 1,704 × 4

```

dplyr::mutate()

• Don't forget to assign the output to a new tibble (or overwrite original) if you want to "save" the new variables!

dplyr::summarize(): create statistics

dplyr::summarize() I

- summarize[†] outputs a tibble of desired summary statistics
 - o can name the statistic variable as if you were mutate -ing a new variable

```
# using the pipe
gapminder %>%
summarize(avg_LE = mean(lifeExp))
```

[†] Also the more civilised non-U.S. English spelling summarise also works. dplyr was written by a Kiwi after all!

dplyr::summarize() II

• Useful summarize() commands:

Command	Does
n()*	Number of observations
<pre>n_distinct()*</pre>	Number of unique observations
sum()	Sum all observations of a variable
mean()	Average of all observations of a variable
<pre>median()</pre>	50 th percentile of all observations of a variable
sd()	Standard deviation of all observations of a variable

^{*} Most commands require you to put a variable name inside the command's argument parentheses. These commands require nothing to be in parentheses!

dplyr::summarize() II

• Useful summarize() commands (continued):

Command	Does
min()	Minimum value of a variable
max()	Maximum value of a variable
quantile(., 0.25)+	Specified percentile (example 25 th percentile) of a variable
first()	First value of a variable
last()	Last value of a variable
nth(., 2) ⁺	Specified position of a variable (example 2 nd)

^{*}The . is where you would put your variable name.

dplyr::summarize() counts

A tibble: 12 × 2

<int> <int>

n

142

year

1 1952

##

• Counts of a categorical variable are useful, and can be done a few different ways:

```
# summarize with n() gives size of current group, has no arguments
gapminder %>%
  summarize(amount = n()) # I've called it "amount"
## # A tibble: 1 x 1
##
     amount
     <int>
##
## 1 1704
# count() is a dedicated command, counts observations by specified variable
gapminder %>%
  count(year) # counts how many observations per year
```

dplyr::summarize() Conditionally

- Can do counts and proportions by conditions
 - How many observations fit specified conditions (e.g. TRUE)
 - Numeric objects: TRUE=1 and FALSE=0
 - sum(x) becomes the number of TRUEs in x
 - mean(x) becomes the proportion

```
# How many countries have life expectancy
                                                        # What *proportion* of countries have life
 # over 70 in 2007?
                                                        # expectancy over 70 in 2007?
gapminder %>%
                                                        gapminder %>%
  filter(year=="2007") %>%
                                                          filter(year=="2007") %>%
   summarize(Over_70 = sum(lifeExp>70))
                                                          summarize(Over_70 = mean(lifeExp>70))
## # A tibble: 1 × 1
                                                       ## # A tibble: 1 × 1
    Over 70
                                                            Over 70
##
                                                       ##
       <int>
                                                              <dbl>
## 1
          83
                                                       ## 1
                                                              0.585
```

dplyr::summarize() Multiple Variables

• Can summarize() multiple *variables* at once, separate by commas

```
## # A tibble: 1 × 2
## avg_LE avg_GDP
## <dbl> <dbl>
## 1 59.5 7215.
```

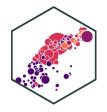

dplyr::summarize() Multiple Statistics

• Can summarize() multiple *statistics* of a variable at once, separate by commas

```
## # A tibble: 1 × 5
## obs avg_LE sd_LE min_LE max_LE
## <int> <dbl> <dbl> <dbl> <dbl> <dbl> ## 1 1704 59.5 12.9 23.6 82.6
```

dplyr::summarize() Multiple Statistics

- "Scoped" versions of summarize() that work on a subset of variables
 - o summarize_all(): affects every variable
 - summarize_at(): affects named or selected variables
 - summarize_if(): affects variables that meet a criteria

```
## # A tibble: 1 × 4
## year_avg lifeExp_avg pop_avg gdpPercap_avg
## <dbl> <dbl> <dbl> <dbl> 7215.
```

```
## # A tibble: 1 × 4
## pop_avg lifeExp_avg `pop_std dev` `lifeExp_std
## <dbl> <dbl> <dbl>
## 1 29601212. 59.5 106157897.
```

dplyr::summarize() with group_by() I

- If we have factor variables grouping a variable into categories, we can run dplyr verbs by group
 - Particularly useful for summarize()
- First define the group with group_by()

```
## # A tibble: 5 × 3
## continent mean_life mean_GDP
## <fct> <dbl> <dbl>
## 1 Africa 48.9 2194.
```

dplyr::summarize() with group_by() II

```
## # A tibble: 12 × 3
       year mean_life mean_GDP
##
                <dbl>
                         <dbl>
##
      <int>
      1952
             49.1
                         3725.
##
                 51.5
                         4299.
##
      1957
##
      1962
                 53.6
                         4726.
##
   4 1967
                 55.7
                         5484.
                 57.6
                         6770.

       1997
                 65.0
                         9090.
```

dplyr::summarize() with group_by() III

• Can group observations by multiple variables (in proper order)

```
# track changes in average life expectancy and gdp by continent over time
gapminder %>%
  group by(continent, year) %>%
  summarize(mean_life = mean(lifeExp),
            mean_GDP = mean(gdpPercap))
## # A tibble: 60 × 4
## # Groups: continent [5]
##
     continent year mean_life mean_GDP
     <fct>
                <int>
                         <dbl>
                                  <dbl>
##
   1 Africa
##
                1952
                          39.1
                                  1253.
##
   2 Africa
               1957
                      41.3
                                  1385.
   3 Africa
                1962
                        43.3
                                  1598.
                          45.3
                                  2050.
##
   4 Africa
                1967
                                  2340.
   5 Africa
                1972
                          47.5
                                  2586.
##
   6 Africa
                1977
                           49.6
   7 Africa
                           51.6
                                  2482.
                 1982
```

Example: Piping Across Packages

- tidyverse uses same grammar and design philosophy
- **Example**: graphing change in average life expectancy by continent over time

```
gapminder %>%
group by(continent, year) %>%
summarize(mean_life = mean(lifeExp),
        mean_GDP = mean(gdpPercap)) %>%
# now pipe this tibble in as data for ggplot!
ggplot(data = ., # . stands in for stuff ^!
     aes(x = year,
         y = mean_life,
         color = continent))+
geom_path(size=1)+
labs(x = "Year",
   y = "Average Life Expectancy (Years)",
   color = "Continent",
   title = "Average Life Expectancy Over Time
theme_classic(base_family = "Fira Sans Conden:
```

Average Life Expectancy Over Time Average Life Expectancy (Years) Continent **Africa Americas** Europe Oceania 1980 1950 1960 1970 1990 2000 Year

dplyr: Other Useful Commands I

• tally provides counts, best used with group_by for factors

gapminder %>%

```
gapminder %>%
  group_by(continent) %>%
  tally
```

```
## # A tibble: 5 × 2
    continent
##
##
    <fct>
              <int>
## 1 Africa
                 624
## 2 Americas
                300
## 3 Asia
                 396
                 360
## 4 Europe
## 5 Oceania
                 24
```

dplyr: Other Useful Commands II

1967 66.2 1984060

1972 67.7 2263554

2 Albania Europe

3 Albania Europe

• slice() subsets rows by position instead of filter ing by values

```
gapminder %>%
  slice(15:17) # see 15th through 17th observations

## # A tibble: 3 × 6

## country continent year lifeExp pop gdpPercap

## <fct> <fct> <int> <dbl> <int> <dbl>
## 1 Albania Europe 1962 64.8 1728137 2313.
```

2760.

3313.

dplyr: Other Useful Commands III

• pull() extracts a column from a tibble (just like \$)

```
# Get all U.S. life expectancy observations
gapminder %>%
  filter(country == "United States") %>%
  pull(lifeExp)
   [1] 68.440 69.490 70.210 70.760 71.340 73.380 74.650 75.020 76.090 76.810
## [11] 77.310 78.242
# Get U.S. life expectancy in 2007
gapminder %>%
  filter(country == "United States" & year == 2007) %>%
  pull(lifeExp)
```

[1] 78.242

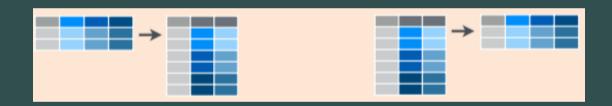

dplyr: Other Useful Commands IV

• distinct() shows the distinct values of a specified variable (recall n_distinct() inside summarize() just gives you the *number* of values)

```
gapminder %>%
  distinct(country)
## # A tibble: 142 × 1
##
      country
##
      <fct>
    1 Afghanistan
    2 Albania
    3 Algeria
    4 Angola
    5 Argentina
    6 Australia
    7 Austria
    8 Bahrain
    9 Bangladesh
   10 Belgium
```

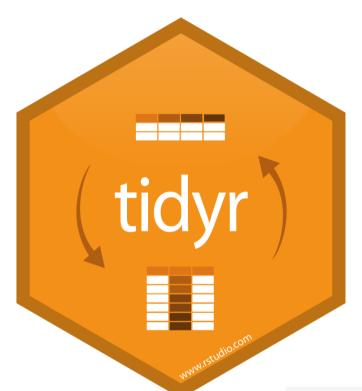

tidyr: reshaping data

tidyr: reshaping and tidying data

- tidyr helps reshape data into more usable format
- "tidy" data[†] are (an opinionated view of) data where
- 1. Each variable is in a column
- 2. Each **observation** is a **row**
- 3. Each observational unit forms a table[‡]
- Spend less time fighting your tools and more time on analysis!

- [†] This is the namesake of the tidyverse: all associated packages and functions use or require this data format!
- [‡] Alternatively, sometimes rule 3 is "every value is its own cell."

tidyr: Tidy Data

"tidy" data ≠ clean, perfect data

"Happy families are all alike; every unhappy family is unhappy in its own way." - Leo Tolstoy

"Tidy datasets are all alike, but every messy dataset is messy in its own way." - Hadley Wickham

tidyr::gather() wide to long I

```
# make example untidy data
ex_wide<-tribble(
    ~"Country", ~"2000", ~"2010",
    "United States", 140, 180,
    "Canada", 102, 98,
    "China", 111, 123
)
ex_wide</pre>
```

```
## # A tibble: 3 × 3
                   `2000` `2010`
##
     Country
##
     <chr>
                    <dbl> <dbl>
## 1 United States
                      140
                             180
## 2 Canada
                      102
                             98
## 3 China
                      111
                              123
```

• Common source of "un-tidy" data:

Column headers are values, not variable names!

- Column names are *values* of a year variable!
- Each row represents *two* observations (one in 2000 and one in 2010)!

tidyr::gather() wide to long II

```
# make example untidy data
ex_wide<-tribble(
    ~"Country", ~"2000", ~"2010",
    "United States", 140, 180,
    "Canada", 102, 98,
    "China", 111, 123
)
ex_wide</pre>
```

```
## # A tibble: 3 × 3
                    `2000` `2010`
##
     Country
##
     <chr>
                    <dbl> <dbl>
## 1 United States
                       140
                              180
## 2 Canada
                       102
                               98
## 3 China
                       111
                              123
```

- We need to gather() these columns into a new pair of variables
 - set of columns that represent values,
 not variables (2000 and 2010)
 - key: name of variable whose values form the column names (we'll call it the year)
 - value: name of the variable whose values are spread over the cells (we'll call it number of cases)

tidyr::gather() wide to long III

• gather() a wide data frame into a long data frame

```
ex wide
## # A tibble: 3 × 3
##
    Country `2000` `2010`
    <chr>
           <dbl> <dbl>
##
## 1 United States
                    140
                          180
## 2 Canada
                    102
                         98
## 3 China
                    111
                          123
```

```
## # A tibble: 6 × 3
    Country year cases
##
##
    <chr> <chr> <chr> <dbl>
## 1 United States 2000
                          140
## 2 Canada
                  2000
                          102
## 3 China
                  2000
                          111
## 4 United States 2010
                          180
## 5 Canada
                  2010
                         98
## 6 China
                  2010
                          123
```

tidyr::spread() long to wide I

```

- We need to spread() these columns into a new pair of variables
 - key: column that contains variable names (here, the type)
 - value: column that contains values from multiple variables (here, the count)

tidyr::spread() long to wide III

• spread() a long data frame into a wide data frame

Combining Datasets

Combining Datasets

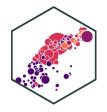

- Often, data doesn't come from just one source, but several sources
- We can combine datasets into a single dataframe (tibble) using dplyr commands in several ways:
 - 1. bind dataframes together by row or by column
 - bind_rows() adds observations (rows) to existing dataset¹
 - bind_cols() adds variables (columns) to existing dataset²
 - 2. join two dataframes by designating variable(s) as key to match rows by identical values of that key

[†] Note the columns must be identical between the original dataset and the new observations

^{*} Note the rows must be identical between original dataset and new variable

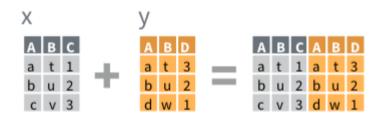

Two Similar Datasets I

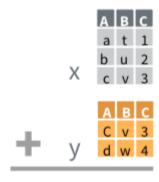

- Sometimes you want to add rows (observations) or columns (variables) that happen to match up perfectly
 - New observations contain all the same variables as existing data
 - \circ OR
 - New variables contain all the same observations as existing data
- In this case, simply using bind_*(old_df, new_df) will work
 - bind_columns(old_df, new_df) adds columns from new_df to old_df
 - bind_rows(old_df, new_df) adds rows from new_df to old_df

Two Similar Datasets II

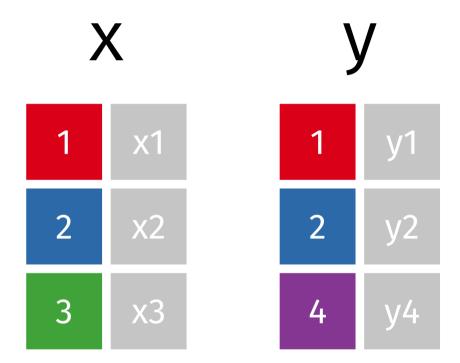

Two **Different** Datasets

- For the following examples, consider the following two dataframes, x and y*
 - each has one unique variable, x\$x and
 y\$y
 - both have values for observations 1 and 2
 - x has observation 3 which y does not have
 - y has observation 4 which x does not have
- We next consider the ways we can merge dataframes x and y into a single dataframe

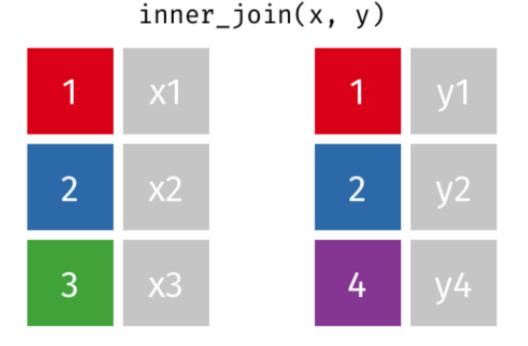

^{*} Images on all following slides come from Garrick Aden-Buie's excellent tidyexplain

Inner-Join

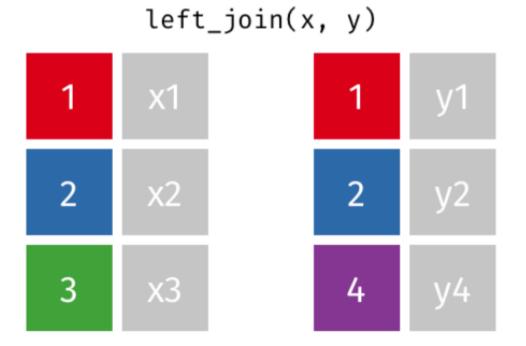

- Merge columns from x and y for which there are matching rows
 - Rows in x with no match in y (3) will be dropped
 - Rows in y with no match in x (4) will be dropped

Left-Join

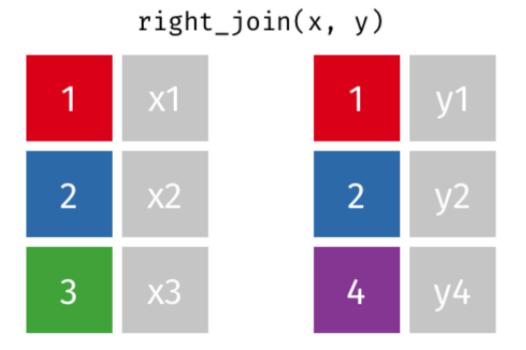

- Start with all rows from x and add all columns from y
 - Rows in x with no match in y (3) will have NAs
 - Rows in y with no match in x (4) will be dropped

Right-Join

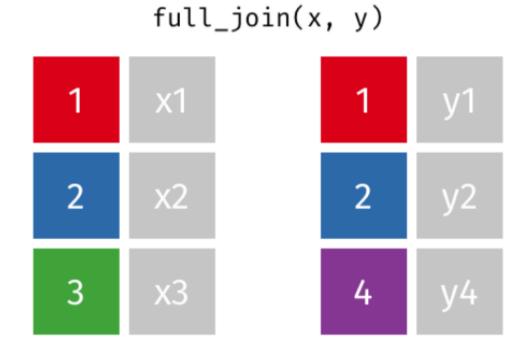

- Start with all rows from y and add all columns from x
 - Rows in y with no match in x (4) will have NAs
 - Rows in x with no match in y (3) will be dropped

Full-Join

- All rows and all columns from x and y
 - Rows that do not match (3 and 4) will have NAs
